2.1.16

(a) Interesting adjoint functors to G -sets.

The trivial group functor I sends a set to a \mathbf{G} -set with the trivial action $gx = x$.
Interesting functors

Orbit functor sends a G -set with underlying set elements a of A to:

$$A_G = \{g \cdot a, g \in G\}$$

Fixed point functor sends a G -set with underlying set elements a of A to:

$$A^G = \{a \text{ such that } g \cdot a = a \text{ for all } g \in G, a \in A\}$$

Fixed point functor - right adjoint Morphisms in a G -set are functions on the underlying set, where f commutes with g for every $g \in G$.

There is a bijection for each $A \in \mathbf{Set}$ and $B \in [G, \mathbf{Set}]$ as follows

$$\begin{aligned} [G, \mathbf{Set}](I(A), B) &\rightarrow \mathbf{Set}(A, B^G) \\ \psi &\mapsto \bar{\psi} \end{aligned}$$

$\bar{\psi}$ sends each element a of A to $\psi(a)$ if $g \cdot a = a$, otherwise it sends a to $\psi(\emptyset)$.

$$\begin{aligned} \mathbf{Set}(A, B^G) &\rightarrow [G, \mathbf{Set}](I(A), B) \\ \phi &\mapsto \bar{\phi} \end{aligned}$$

ϕ sends each $a \in A$ in the underlying set of the G -set to the G -set $(g, \bar{\phi}(a)), g \in G$.

Orbit functor - left adjoint There is a bijection for each $A \in [G, \mathbf{Set}]$ and $B \in \mathbf{Set}$ as follows

$$\begin{aligned} \mathbf{Set}(A_G, B) &\rightarrow [G, \mathbf{Set}](A, I(B)) \\ \psi &\mapsto \bar{\psi} \end{aligned}$$

So each morphism in \mathbf{Set} sends the set formed by the orbits of an element a of A , call this a_G , to $\psi(a_G)$, where ψ is a function of sets. Choose a G -set morphism $\bar{\psi} = \psi$, where $\bar{\psi}$ commutes with g for every g in G .

$$\begin{aligned} [G, \mathbf{Set}](A, I(B)) &\rightarrow \mathbf{Set}(A_G, B) \\ \phi &\mapsto \bar{\phi} \end{aligned}$$

Choose $\bar{\phi}$ to be a disjoint union of each orbit of a in A , $\bar{\phi}(a) = \coprod \{\phi(g \cdot a), g \in G\}$

2.1.17

Write $\mathcal{O}(X)$ for the poset of open subsets of a topological space X ordered by inclusion.

$$\Delta : \mathbf{Set} \rightarrow [\mathcal{O}(X)^{op}, \mathbf{Set}]$$

Write \mathcal{P} for the presheaf functor category, and $P \in \mathcal{P}$ for the functor which maps $\mathcal{O}(X)^{op}$ to \mathbf{Set} . Take open sets U, V , such that $U \subseteq V$ in X . A presheaf consists of

- restriction maps, $P(V) \rightarrow P(U)$, these are morphisms which enforce some sort of ordering of the mapped sets,
- and the actual mapped sets $P(U), P(V)$ which are called sections.

Write $\Gamma P = P(X)$ for the **global** sections functor which takes an element of \mathcal{P} to a \mathbf{Set} .

Intuition Defining the sections functor to map the entire space in this way means in \mathbf{Set} we have a map into every section. You can think of the presheaf as loosely a blueprint on how to sort the sections. So if we provide a presheaf sorting some of these sections, and a mapping of these sections, then we can get back a new presheaf sorting the mapped sections.

For A in \mathbf{Set} and B in \mathcal{P}

$$\begin{aligned} \mathbf{Set}(A, \Gamma B) &\rightarrow \mathcal{P}(\Delta A, B) \\ \phi &\mapsto \phi \circ P \end{aligned}$$

In \mathcal{P} we take $\phi \circ P$ as the presheaf functor.
