3.1.1

There are bijections

$$(A + B, C) \leftrightarrow ((A, B), \Delta C)$$

$$f \leftrightarrow \bar{f}$$

where $\bar{f} = (f, f)$

$$(\Delta A, (B, C)) \leftrightarrow (A, B \times C)$$

$$g = (p, q) \leftrightarrow \bar{g}$$

where $\bar{g}(x) = (p(x), q(x))$

So the sum is left adjoint to Δ , and the product is its right adjoint.

3.1.2

We are given the definition of a sequence, where there is a unique function x such that the square below commutes.

We have $x_0 = a$, and $x_{n+1} = r(x_n)$.

$$\begin{array}{ccc} \mathbb{N} & \xrightarrow{s} & \mathbb{N} \\ \downarrow x & & \downarrow x \\ X & \xrightarrow{r} & X \end{array}$$

This is precisely the definition of the comma category $(\mathbb{N} \Rightarrow X)$, where objects are $(n \in \mathbb{N}, x, t \in X)$.

3.2.12

(a)

$$\theta(S) = \bigcup \theta(R) \supseteq \bigcup R = S$$

But $\theta^2(S) = \theta(S)$, so $\theta(S) \subseteq S$.

Taken together, the above implies $\theta(S) = S$.

(b)

$$\begin{aligned} A &\subseteq B \\ \implies fA &\subseteq fB \\ \implies gfA &\subseteq gfB \end{aligned}$$

g and f are taken to be injections here. We need to prove there is a bijection between A and B . **Note:** this does not follow immediately from g and f being injections.

Take $\theta(S) = A - g(B \setminus fS)$. Then $S_1 \subseteq S_2 \implies \theta(S_1) \subseteq \theta(S_2)$. Since f, g and hence θ is order preserving, we may apply the result in (a). Specifically, there exists S such that $S = A - g(B \setminus fS) \implies g(B \setminus fS) = A \setminus S$.

(c) We need to prove a bijection between A and B to deduce the theorem. Consider $h: A \rightarrow B$

$$h(x) = \begin{cases} f(x), & x \in S, \\ g^{-1}(x), & x \in A \setminus S \end{cases}$$

f has a codomain of fS , so every element of the codomain has a preimage in S . We are given that f is injective.

g is injective and hence invertible. Using the result in (b) we have a direct expression for g^{-1} . Hence we have $gh = 1_A$, and $hg = 1_B$, for x in $A \setminus S$.

3.2.14

Need to prove that for any family $(A_i)_{i \in I}$ of objects of \mathcal{A} , there is some object of \mathcal{A} not isomorphic to A_i for $i \in I$. It suffices to prove for A in $F(S)$, $F: \mathbf{Set} \rightarrow \mathcal{A}$, then we know the condition holds for \mathcal{A} . Now UF is injective by Exercise 2.3.11, so U is injective on objects A of $F(S)$. So if UA_i is not isomorphic to UA_j ,

this would imply A_i is not isomorphic to A_j . So we need to prove for a given i , $|UA_i| < |\mathcal{P}(UA)|$:

$$|UA_i| \leq |\Sigma UA_i| < |\mathcal{P}(UA)|$$

The strict equality due to Theorem 3.2.2.

3.2.15

(a) **Mon** is equivalent to a single object category, which is small. So **Mon** is essentially small.

(b) \mathbb{Z} , the group of integers viewed as a one object category, is small. The maps between integers form a set, if \mathbb{Z} has n elements, then the morphisms between them have n^2 elements.

(c) The ordered set of integers have one map between each so form a set, hence it is a small category.

(d) ??

(e) **Guess.** Same as (a). Cardinals are just a set, and morphisms between them form a set, so essentially small.
