2.1.16

(a)   Interesting adjoint functors to G-sets.

The trivial group functor I sends a set to a **G**-set with the trivial action $gx = x$. Interesting functors

Orbit functor sends a G-set with underlying set elements a of A to:

$A_G = \{g \cdot a, g \in G\}$

Fixed point functor sends a G-set with underlying set elements a of A to:

$A^G = \{a \text{ such that } g \cdot a = a \text{ for all } g \in G, a \in A\}$

Fixed point functor - right adjoint   Morphisms in a G-set are functions on the underlying set, where f commutes with g for every $g \in G$.

There is a bijection for each $A \in \mathbf{Set}$ and $B \in [G, \mathbf{Set}]$ as follows

$$[G, \mathbf{Set}](I(A), B) \to \mathbf{Set}(A, B^G)$$
$$\psi \mapsto \overline{\psi}$$

$\overline{\psi}$ sends each element a of A to $\psi(a)$ if $g \cdot a = a$, otherwise it sends a to $\psi(\emptyset)$.

$$\mathbf{Set}(A, B^G) \to [G, \mathbf{Set}](I(A), B)$$
$$\phi \mapsto \overline{\phi}$$

ϕ sends each $a \in A$ in the underlying set of the G-set to the G-set $(g, \overline{\phi}(a)), g \in G$.

Orbit functor - left adjoint   There is a bijection for each $A \in [G, \mathbf{Set}]$ and $B \in \mathbf{Set}$ as follows

$$\mathbf{Set}(A_G, B) \to [G, \mathbf{Set}](A, I(B))$$
$$\psi \mapsto \overline{\psi}$$

So each morphism in $\mathbf{Set}$ sends the set formed by the orbits of an element a of A, call this a_G, to $\psi(a_G)$, where ψ is a function of sets. Choose a G-set morphism $\overline{\psi} = \psi$, where $\overline{\psi}$ commutes with g for every g in G.

$$[G, \mathbf{Set}](A, I(B)) \to \mathbf{Set}(A_G, B)$$
$$\phi \mapsto \overline{\phi}$$

Choose $\overline{\phi}$ to be a disjoint union of each orbit of a in A, $\overline{\phi}(a) = \amalg\{\phi(g \cdot a), g \in G\}$

2.1.17

Write $\mathcal{O}(X)$ for the poset of open subsets of a topological space X ordered by inclusion.

$\Delta : \mathbf{Set} \to [\mathcal{O}(X)^{op}, \mathbf{Set}]$

Write $\mathcal{P}$ for the presheaf functor category, and $P \in \mathcal{P}$ for the functor which maps $\mathcal{O}(X)^{op}$ to $\mathbf{Set}$. Take open sets U, V, such that $U \subseteq V$ in X. A presheaf consists of

- restriction maps, $P(V) \to P(U)$, these are morphisms which enforce some sort of ordering of the mapped sets,

- and the actual mapped sets $P(U), P(V)$ which are called sections.

Since the question specifies a constant presheaf, by definition, the restriction maps of ΔA are identity maps. And the sections are just the A. Specifically $\Delta A(U) = A$ for subsets U of X, and $\Delta A(\to) = 1_A$ for morphisms.

Write $\Gamma P = P(X)$ for the **global** sections functor which takes an element of $\mathcal{P}$ to a $\mathbf{Set}$.

We are required to show a bijection:

For A in $\mathbf{Set}$ and B in $\mathcal{P}$

$$\mathbf{Set}(A, \Gamma B) \to \mathcal{P}(\Delta A, B)$$

and

$$\mathcal{P}(\Delta A, B) \to \mathbf{Set}(A, \Gamma B)$$

The maps between the presheaf functors in $\mathcal{P}$ are natural transformations. Natural transformations are a collection of maps $\alpha_A\colon \{\Delta A(A) \to B(A)\}_{A \in \mathcal{A}}$. For $U \subseteq V \subseteq X$ we have the commuting square:

$$
\begin{array}{ccccc}
\Delta A(X) & \xrightarrow{\ 1_A\ } & \Delta A(V) & \xrightarrow{\ 1_A\ } & \Delta A(U) \\
\downarrow{\scriptstyle \alpha_X} & & \downarrow{\scriptstyle \alpha_V} & & \downarrow{\scriptstyle \alpha_U} \\
B(X) & \xrightarrow{\ B(f)\ } & B(V) & \xrightarrow{\ B(f)\ } & B(U)
\end{array}
\qquad (1)
$$

Recall $\Delta A(\cdot) = A$. Then the morphism in $\mathbf{Set}$ is represented by α_X above. As visible from the figure above this corresponds one to one with each α_A in $\mathcal{A}$, so the bijection holds. Dually using the exact same reasoning Π, the left adjoint of Δ is the presheaf evaluation at the empty set, $\Pi(P) = P(\emptyset)$.

For the left adjoint to Π, Λ, and for A in $\mathbf{Set}$ and B in $\mathcal{P}$, we need to show a bijection between:

$$\mathcal{P}(\Lambda A, B) \leftrightarrow \mathbf{Set}(A, \Pi(B))$$

To try and cobble together a definition of the presheaf functor Λ, start with the naturality diagram representing morphisms in $\mathcal{P}$:

$$
\begin{array}{ccc}
\Lambda(U) & \xrightarrow{\ A(f)\ } & \Lambda(\emptyset) \\
\downarrow{\scriptstyle \alpha_U} & & \downarrow{\scriptstyle \alpha_\emptyset} \\
B(U) & \xrightarrow{\ B(f)\ } & B(\emptyset)
\end{array}
$$

Note that $\Pi(B) = B(\emptyset)$. Start by choosing $\Lambda(\emptyset) = A$, so the morphism in $\mathbf{Set}$ is $\alpha_\emptyset$. Our choice of Λ needs to make this diagram commute for all U in $\mathcal{O}(X)^{op}$. For $U \neq \emptyset$ we could try $\Lambda(U) = A$, however to force the square above to commute with this choice, will impose some structure on the presheaf B. Rather, try setting $\Lambda(U) = \emptyset$ for $U \neq \emptyset$. Choosing the initial object $\emptyset$ of $\mathcal{O}(X)^{op}$, means there is one map out of the top LHS of the square in the above diagram, and the square commutes as required.

We also have

$$\mathcal{P}(A, \nabla B) \leftrightarrow \mathbf{Set}(\Gamma A, B)$$

∇, the right adjoint to Γ can be obtained dually, by swapping $\mathbf{Set}$ with $\mathbf{Set}^{op}$ and $\mathcal{O}(X)^{op}$ with $\mathcal{O}(X)$. This is simply a relabelling which has the effect of reversing the chain of adjoint functors stated in the question. We then apply analogous reasoning, take $\nabla(U) = \{*\}$, for $U \neq X$, and $\nabla(X) = B$.

2.2.11

The full subcategory where η_a is an isomorphism

2.2.13

We have sets S, T, a function $f \colon S \to T$. $P(S)$ denotes the set of all subsets of S. The functor f^* takes elements of T to their inverse under f. Looking for left and right adjoints of f^*. We can immediately see the left adjoint of f^* is f from below.

$$P(S)(A, f^{-1}(B)) \cong P(T)(f(A), B) \tag{2}$$

Now to find the right adjoint of f^*, G below:

$$P(T)(A, G(B)) \cong P(S)(f^{-1}(A), B)$$

Dualising

$$P(T)^{op}(G(B), A) \cong P(S)^{op}(B, f^{-1}(A)) \tag{3}$$

Equation (3) is (2) up to an isomorphism. So we choose $G = f$ here. In fact the power set P is self adjoint. Loosely, this means we have an isomorphism between the opposite category and the original category. We use this isomorphism to get a representation of G in $P(T)$, with the right adjoint sending B to $\overline{f(\overline{B})}$.

Because f is a bijection, elements in T that are not in $f(\overline{B})$ must have elements in B as their preimage. So $\overline{f(\overline{B})}$ consists of all sets of T where $f^{-1}(T) \subseteq B$. This could indeed be empty. In summary the left adjoint of f^* is

$$\{f(s), s \in S\}$$

and the right adjoint

$$\{t \in T : f^{-1}(t) \subseteq S\}$$

The unit $\eta \colon 1_T \to G \circ F$, and counit $\epsilon \colon F \circ G \to 1_S$

The unit returns a predicate $S(x)$ implying $P(x, y)$ if it exists, otherwise the empty set.

The counit returns all predicates $S(x)$, or none, implied by $P(x, y)$
